And to my wife, Arlene, for her attention-to-detail approach to life, especially
when juxtaposed to my 'big picture' way of doing things.*

Contents

Preface	xiii
About the Author.....	xvii

CHAPTER 1	Introduction	1
1.1	Motion perception.....	2
1.2	The heritage of animation	4
1.2.1	Early devices.....	4
1.2.2	The early days of “conventional” animation	6
1.2.3	Disney	7
1.2.4	Contributions of others.....	8
1.2.5	Other media for animation	8
1.3	Animation production.....	9
1.3.1	Principles of animation.....	10
1.3.2	Principles of filmmaking	12
1.3.3	Sound	14
1.4	Computer animation production.....	15
1.4.1	Computer animation production tasks	16
1.4.2	Digital editing	18
1.4.3	Digital video	20
1.4.4	Digital audio	21
1.5	A brief history of computer animation	22
1.5.1	Early activity (pre-1980)	22
1.5.2	The middle years (the 1980s).....	25
1.5.3	Animation comes of age (the mid-1980s and beyond)	26
1.6	Summary.....	29

CHAPTER 2	Technical Background.....	33
2.1	Spaces and transformations	33
2.1.1	The display pipeline	34
2.1.2	Homogeneous coordinates and the transformation matrix	38
2.1.3	Concatenating transformations: multiplying transformation matrices	40
2.1.4	Basic transformations	40
2.1.5	Representing an arbitrary orientation.....	42
2.1.6	Extracting transformations from a matrix.....	46
2.1.7	Description of transformations in the display pipeline.....	47
2.1.8	Error considerations.....	48

2.2	Orientation representation	52
2.2.1	Fixed-angle representation	54
2.2.2	Euler angle representation	56
2.2.3	Angle and axis representation	57
2.2.4	Quaternion representation.....	58
2.2.5	Exponential map representation.....	60
2.3	Summary	60
CHAPTER 3	Interpolating Values	61
3.1	Interpolation.....	61
3.1.1	The appropriate function	62
3.1.2	Summary	65
3.2	Controlling the motion of a point along a curve	65
3.2.1	Computing arc length	66
3.2.2	Speed control	78
3.2.3	Ease-in/ease-out	80
3.2.4	General distance-time functions.....	86
3.2.5	Curve fitting to position-time pairs.....	90
3.3	Interpolation of orientations	91
3.3.1	Interpolating quaternions	91
3.4	Working with paths	96
3.4.1	Path following.....	96
3.4.2	Orientation along a path.....	96
3.4.3	Smoothing a path.....	100
3.4.4	Determining a path along a surface	106
3.4.5	Path finding.....	108
3.5	Chapter summary.....	108
CHAPTER 4	Interpolation-Based Animation	111
4.1	Key-frame systems	111
4.2	Animation languages	115
4.2.1	Artist-oriented animation languages	116
4.2.2	Full-featured programming languages for animation	116
4.2.3	Articulation variables	117
4.2.4	Graphical languages	117
4.2.5	Actor-based animation languages	118
4.3	Deforming objects	119
4.3.1	Picking and pulling.....	119
4.3.2	Deforming an embedding space.....	121

4.4	Three-dimensional shape interpolation	135
4.4.1	Matching topology	136
4.4.2	Star-shaped polyhedra	137
4.4.3	Axial slices	137
4.4.4	Map to sphere	139
4.4.5	Recursive subdivision	145
4.5	Morphing (two-dimensional)	147
4.5.1	Coordinate grid approach	147
4.5.2	Feature-based morphing	153
4.6	Chapter summary	159
CHAPTER 5	Kinematic Linkages	161
5.1	Hierarchical modeling	162
5.1.1	Data structure for hierarchical modeling	164
5.1.2	Local coordinate frames	170
5.2	Forward kinematics	171
5.3	Inverse kinematics	172
5.3.1	Solving a simple system by analysis	173
5.3.2	The Jacobian	174
5.3.3	Numeric solutions to IK	178
5.3.4	Summary	185
5.4	Chapter summary	185
CHAPTER 6	Motion Capture	187
6.1	Motion capture technologies	187
6.2	Processing the images	188
6.3	Camera calibration	190
6.4	Three-dimensional position reconstruction	191
6.4.1	Multiple markers	192
6.4.2	Multiple cameras	192
6.5	Fitting to the skeleton	193
6.6	Output from motion capture systems	195
6.7	Manipulating motion capture data	196
6.7.1	Processing the signals	196
6.7.2	Retargeting the motion	197
6.7.3	Combining motions	197
6.8	Chapter summary	198
CHAPTER 7	Physically Based Animation	199
7.1	Basic physics—a review	200
7.1.1	Spring-damper pair	202

7.2	Spring animation examples	202
7.2.1	Flexible objects	202
7.2.2	Virtual springs	205
7.3	Particle systems	205
7.3.1	Particle generation	206
7.3.2	Particle attributes	207
7.3.3	Particle termination	207
7.3.4	Particle animation	207
7.3.5	Particle rendering	207
7.3.6	Particle system representation	208
7.3.7	Forces on particles	208
7.3.8	Particle life span	209
7.4	Rigid body simulation	209
7.4.1	Bodies in free fall	210
7.4.2	Bodies in collision	219
7.4.3	Dynamics of linked hierarchies	232
7.5	Cloth	235
7.5.1	Direct modeling of folds	237
7.5.2	Physically based modeling	240
7.6	Enforcing soft and hard constraints	244
7.6.1	Energy minimization	244
7.6.2	Space-time constraints	247
7.7	Chapter summary	249
CHAPTER 8	Fluids: Liquids and Gases	251
8.1	Specific fluid models	251
8.1.1	Models of water	251
8.1.2	Modeling and animating clouds	262
8.1.3	Modeling and animating fire	268
8.1.4	Summary	270
8.2	Computational fluid dynamics	270
8.2.1	General approaches to modeling fluids	271
8.2.2	CFD equations	272
8.2.3	Grid-based approach	276
8.2.4	Particle-based approaches including smoothed particle hydrodynamics	277
8.3	Chapter summary	280
CHAPTER 9	Modeling and Animating Human Figures	283
9.1	Overview of virtual human representation	283
9.1.1	Representing body geometry	284
9.1.2	Geometry data acquisition	285

9.1.3	Geometry deformation.....	286
9.1.4	Surface detail	286
9.1.5	Layered approach to human figure modeling.....	287
9.2	Reaching and grasping	290
9.2.1	Modeling the arm	290
9.2.2	The shoulder joint.....	293
9.2.3	The hand	293
9.2.4	Coordinated movement.....	295
9.2.5	Reaching around obstacles	296
9.2.6	Strength.....	297
9.3	Walking.....	298
9.3.1	The mechanics of locomotion	298
9.3.2	The kinematics of the walk	303
9.3.3	Using dynamics to help produce realistic motion	303
9.3.4	Forward dynamic control	308
9.3.5	Summary	308
9.4	Coverings	309
9.4.1	Clothing	309
9.4.4	Hair	309
9.5	Chapter summary.....	311
CHAPTER 10	Facial Animation	317
10.1	The human face	317
10.1.1	Anatomic structure	317
10.1.2	The facial action coding system.....	319
10.2	Facial models.....	320
10.2.1	Creating a continuous surface model.....	322
10.2.2	Textures	325
10.3	Animating the face	327
10.3.1	Parameterized models.....	327
10.3.2	Blend shapes.....	327
10.3.3	Muscle models.....	329
10.3.4	Expressions	332
10.3.5	Summary	332
10.4	Lip-sync animation.....	333
10.4.1	Articulators of speech.....	333
10.4.2	Phonemes	334
10.4.3	Coarticulation.....	335
10.4.4	Prosody	335
10.5	Chapter summary.....	335

CHAPTER 11 Behavioral Animation	339
11.1 Primitive behaviors.....	342
11.1.1 Flocking behavior.....	342
11.1.2 Prey–predator behavior.....	351
11.2 Knowledge of the environment.....	352
11.2.1 Vision.....	352
11.2.2 Memory.....	353
11.3 Modeling intelligent behavior	354
11.3.1 Autonomous behavior.....	354
11.3.2 Expressions and gestures.....	356
11.3.3 Modeling individuality: personality and emotions	357
11.4 Crowds	358
11.4.1 Crowd behaviors.....	359
11.4.2 Internal structure.....	359
11.4.3 Crowd control.....	360
11.4.4 Managing <i>n</i> -squared complexity	360
11.4.5 Appearance	361
11.5 Chapter summary.....	361
CHAPTER 12 Special Models for Animation	365
12.1 Implicit surfaces	365
12.1.1 Basic implicit surface formulation.....	365
12.1.2 Animation using implicitly defined objects.....	367
12.1.3 Collision detection.....	368
12.1.4 Deforming the implicit surface as a result of collision	368
12.1.5 Level set methods.....	371
12.1.6 Summary	372
12.2 Plants.....	372
12.2.1 A little bit of botany.....	372
12.2.2 L-systems	374
12.2.3 Animating plant growth.....	379
12.2.4 Summary.....	381
12.3 Subdivision surfaces	382
12.4 Chapter summary.....	384
Appendix A Rendering Issues.....	387
Appendix B Background Information and Techniques.....	407
Index	503

Preface

Overview

This book surveys computer algorithms and programming techniques for specifying and generating motion for graphical objects, that is, *computer animation*. It is primarily concerned with three-dimensional (3D) computer animation. The main audience is advanced undergraduate or beginning graduate students in Computer Science. Computer graphics programmers who want to learn the basics of computer animation programming and artists who use software packages to generate computer animation (*digital animators*) who want to better understand the underlying computational issues of animation software will also benefit from this book.

It should come as no surprise to anyone reading this book that activity in Computer Animation has exploded in recent years - as a research area, as an academic field of study, as a career, and even as a hobby. Feature length films are now often stored digitally and incorporate digital special effects (often referred to as *computer generated imagery* and abbreviated *CGI*). As listed by the Internet Movie Database (imdb.com) [1] as of March 2012, all of the top 10 U.S. films (All-Time U.S. Box Office) depend on extensive use of CGI. Computer animated films have become top box office attractions - according to the same movie database, 2 of the top 10 feature length films are computer animations (*Shrek 2* and *Toy Story 3*) with a third having a significant computer animation component (*Avatar*). Recent *Technical Achievement* and *Scientific and Engineering* awards from the Motion Picture Academy of Arts and Sciences have been for digital image technology including render queue management, facial motion retargeting, tools to review digital effects, and efficient rendering of volumetric effects, just to name a few [2]. And, of course, the computer game industry has exploded. The Entertainment Software Association estimate that, in 2010, consumers spent \$25.1 billion on video games, hardware and accessories [3].

Computer animation is more accessible than ever. Desktop, high-quality, computer animation is now possible because of sophisticated off-the-shelf animation software, cheap CPU cycles, and cheap storage coupled with digital video recording. Many technical programs and computer science departments now offer courses in computer animation and the proliferating artistic programs train digital artists in the use of off-the-shelf animation software. There are now major technical conferences and journals that archive developments in computer animation and video game algorithms and techniques.

This book addresses practical issues, provides accessible techniques, and offers straightforward implementations. Purely theoretical discussions have been avoided except to point out avenues of current and future research. In some cases, programming examples are complete working code segments—in C, which can be copied, compiled, and run to produce basic examples of the algorithms discussed; other programming examples are C-like pseudocode that can be translated into working code. C was chosen because it forms the common basis for languages such as C++ and Java, and it lends itself to illustrating the step-by-step nature of algorithms. The Appendixes cover basic material that the reader may find useful as a refresher as well as specific algorithms for use in implementations.

This text is not intended for animators using off-the-shelf animation software (except to the extent that it might help in understanding the underlying computations required for a particular

technique). It does not attempt to cover the theory of computer animation, address the aesthetics of computer animation, or discuss the artistic issues involved in designing animations. It does not detail the production issues in the actual commercial enterprise of producing a finished piece of animation. And, finally, it does not address the issue of *computer-assisted animation*, which, for our purposes, is taken to mean the computerization of conventional hand-drawn techniques; for the most part, that area has its own set of separate issues [4] [5]. The book does concentrate on full 3D computer animation and identifies the useful algorithms and techniques that animators and programmers can use to move objects in interesting ways. While 3D techniques are the emphasis, 2D is not completely ignored.

The fundamental objective of computer animation programming is to select techniques and design tools that are expressive enough for animators to specify what they intend, yet at the same time are powerful enough to relieve animators from specifying any details they are not interested in. Obviously, no one tool is going to be right for every animator, for every animation, or even for every scene in a single animation. The appropriateness of a particular animation tool depends on the effect desired and the control required by the animator. An artistic piece of animation will usually require tools different from those required by an animation that simulates reality or educates a patient. In this spirit, alternative approaches are presented whenever possible.

Organization of the Book

This book presents background information in the first couple of chapters. Techniques that directly specify motion (*kinematic* - not based on underlying forces) are presented in the next 4 chapters followed by 2 chapters that cover force-based (*dynamics*) animation. Character animation is then covered in 3 chapters. The last chapter covers special geometric models. Appendices provide extensive support material. More detail about the chapters is given below.

Chapter 1 discusses general issues related to animation, including motion perception, the heritage of conventional animation paying particular attention to its technological innovations, overviews of animation production and computer animation production, and a snapshot of the ever-evolving history of computer animation. These provide a broad perspective of the art and craft that is animation.

Chapter 2 presents background material and reviews the basics of computer graphics necessary for animation. It reviews computational issues in computer graphics to ensure a solid background in the techniques that are important in understanding the remainder of the book. This includes a review of the rendering pipeline and a discussion of the ordering of transformations to reduce round-off errors that can creep into a series of calculations as one builds on another. A detailed section on quaternion representation of orientation is presented in this chapter as well. If the reader is well versed in computer graphics, this chapter may be skimmed to pick up relevant terminology or skipped altogether.

Chapters 3 and 4 cover interpolation. Chapter 3 presents the fundamentals. It introduces time-space curves, arc-length parameterization of a curve, and speed control along a curve. Interpolation of orientation with an emphasis on using quaternions is then covered. Various ways to work with paths are then presented. Chapter 4 presents animation techniques based on interpolation including key frame interpolation, animation languages, shape deformation, and shape interpolation including morphing.

Chapters 5 and 6 are primarily concerned with kinematic control of articulated figures. Chapter 5 is concerned with kinematics of linked appendages. It covers both forward and inverse kinematics. Chapter 6 covers the basics of motion capture (*mocap*). First, the basic technology is reviewed. Then the chapter discusses how the images are processed to reconstruct articulated figure kinematics, including some techniques to modify the resultant mocap data.

Chapters 7 and 8 cover animation that is more concerned with simulating real-world (e.g. physics-based) processes. Chapter 7 covers physics-based animation as well as mass-spring-damper systems, particle systems, rigid body dynamics, and enforcing constraints. It has an additional section on ways to model cloth. Chapter 8 covers the modeling and animation of fluids. It first covers models that handle specific macro-features of fluids and then covers computational fluid dynamics (CFD) as it relates to computer animation.

Chapters 9 through 11 cover animation concerned with people and other critters. Chapter 9 covers human figure animation: modeling, reaching, walking, clothing, and hair. Chapter 10 covers facial animation: facial modeling, expressions, and lip-sync animation. Chapter 11 covers behavioral animation including flocking, predator-prey models, intelligent behavior and crowd behavior.

Finally, Chapter 12 covers a few special models that are useful to animation: implicit surfaces, L-systems, and subdivision surfaces.

Appendix A presents rendering issues often involved in producing images for computer animation: double buffering, compositing, computing motion blur, drop shadows, and billboard. It assumes a general knowledge of the use of frame buffers, how a z-buffer display algorithm works, and aliasing.

Appendix B is a collection of relevant material from a variety of disciplines. It contains a survey of interpolation and approximation techniques, vector algebra and matrices, quaternion conversion code, the first principles of physics, several useful numeric techniques, optimization, and attributes of film, video, and image formats, and a few other topics.

The Web page associated with the book, containing images, code, and figures can be found at textbooks.elsevier.com/9780125320009.

Acknowledgments

Many people contributed in various ways to this book. First and foremost, I'd like to thank my wife, Arlene, who both tolerated my preoccupation with this project and greatly increased the readability of the book.

In general, I owe much to the students I have had the pleasure of knowing and/or working with over the years and whose collective interest in, knowledge of, and enthusiasm for the field has fueled my own. Their contribution cannot be overstated. These include Doug Roble, John Chadwick, Dave Haumann, Dave Ebert, Matt Lewis, Karan Singh, Steve May, James Hahn, Ferdi Scheepers, Dave Miller, Beth Hofer, Madhavi Muppala, Domin Lee, Kevin Rogers, Brent Watkins, Brad Winemiller, Meg Geroch, Lawson Wade, Arun Somasundaram, Scott King, and Scott (Slim) Whitman (apologies to anyone left out).

I would also like to thank the readers who, over the years, have given me feedback (both good and bad) concerning the book. In particular, I would like to note the critical contributions of Dr. Philip Schlup of Colorado State University, Dr. Brian Wyvill of the University of Calgary, and Dr. Przemyslaw Kiciak of the University of Warsaw.

And finally, I would like to acknowledge the support of the Department of Computer Science and Engineering at Ohio State (Xiaodong Zhang, Chair) as well as the support of the Advanced Computing Center for Art and Design (Maria Palazzi, Director). I would also like to thank Morgan Kaufmann's reviewers and multiple editors for seeing this project through.

About the Author

Rick Parent is a Professor in the Computer Science and Engineering Department of Ohio State University (OSU). As a graduate student, Rick worked at the Computer Graphics Research Group (CGRG) at OSU under the direction of Charles Csuri. In 1977, he received his Ph.D. from the Computer and Information Science (CIS) Department, majoring in Artificial Intelligence. For the next three years, he worked at CGRG first as a Research Associate, and then as Associate Director. In 1980 he co-founded and was President of The Computer Animation Company. In 1985, he joined the faculty of the CIS Department (now the Department of Computer -Science and Engineering) at Ohio State. Rick's research interests include various aspects of computer animation with special focus on animation of the human figure. Currently, he is working on facial animation and on using model-based techniques to track human figures in video.

Introduction

1

Computer animation, for many people, is synonymous with big-screen events such as *Star Wars*, *Toy Story*, and *Avatar*. But not all, or arguably even most, computer animation is done in Hollywood. It is not unusual for Saturday morning cartoons to be entirely computer generated. Computer games take advantage of state-of-the-art computer graphics techniques and have become a major motivating force driving research in computer animation. Real-time performance-driven computer animation has appeared at SIGGRAPH¹ and on *Sesame Street*. Desktop computer animation is now possible at a reasonable cost. Computer animation on the Web is routine. Digital simulators for training pilots, SWAT teams, and nuclear reactor operators are commonplace. The distinguishing characteristics of these various venues are the cost, the image quality desired, and the amount and type of interaction allowed. This book does not address the issues concerned with a particular venue, but it does present algorithms and techniques used to do computer animation in all of them.

Computer animation, as used here, refers to any computer-based computation used in producing images intended to create the perception of motion. The emphasis in this book is on algorithms and techniques that process three-dimensional graphical data. In general, any value that can be changed can be animated. An object's position and orientation are obvious candidates for animation, but all of the following can be animated as well: the object's shape, its shading parameters, its texture coordinates, the light source parameters, and the camera parameters.

This book is organized as follows. To lay a firm foundation for the rest of the book, [Chapter 2](#) surveys the technical background of computer graphics relevant to computer animation. This includes the fundamental geometric transformations and associated representations of graphical data. It can be skipped by those well versed in the mathematics of the computer graphics display pipeline. [Chapters 3–11](#) cover various computer animation algorithms and techniques: [Chapters 3–5](#) deal with directly specifying motion (kinematics), [Chapter 6](#) covers digitizing motion (motion capture), [Chapters 7 and 8](#) consider physically based animation (dynamics), and [Chapters 9–11](#) concentrate on (mostly human) figure animation. Finally, [Chapter 12](#) surveys some modeling techniques that have been used in computer animation. The appendices provide ancillary material. [Appendix A](#) covers rendering issues that are relevant for animation, and [Appendix B](#) provides detail of the mathematics used in the text.

In considering computer animation techniques, there are basically three general approaches to motion control. The first is *artistic animation* in which the animator has the prime responsibility for crafting the motion. The foundation of artistic animation is interpolation. Various animation

¹SIGGRAPH is the Association for Computing Machinery's (ACM) special interest group on computer graphics. The ACM is the main professional group for computer scientists.

techniques based on interpolation are concentrated in the early chapters (Chapters 3–5). The second is *data-driven animation* in which live motion is digitized and then mapped onto graphical objects. The primary technology for data-driven animation is referred to as *motion capture* and is the topic of Chapter 6. The third is *procedural animation*, in which there is a computational model that is used to control the motion. Usually, this is in the form of setting initial conditions for some type of physical or behavioral simulation. Procedural animation is concentrated in the later chapters (Chapters 7–11).

To set the context for computer animation, it is important to understand its heritage, its history, and certain relevant concepts. The rest of this chapter discusses motion perception, the technical evolution of animation, animation production, and notable works in computer animation. It provides a grounding in computer animation as a field of endeavor.

1.1 Motion perception

A picture can quickly convey a large amount of information because the human visual system is a sophisticated information processor. It follows, then, that moving images have the potential to convey even more information in a short time. Indeed, the human visual system has evolved to provide for survival in an ever-changing world; it is designed to notice and interpret movement.

It is widely recognized that a series of images, when displayed in rapid succession, are perceived by an observer as a single moving image. This is possible because the eye–brain complex has the ability, under sufficient viewing conditions and within certain playback rates, to create a sensation of continuous imagery from such a sequence of still images. A commonly held view is that this experience is due to *persistence of vision*, whereby the eye retains a visual imprint of an image for a brief instant once the stimulus is removed. It is argued that these imprints, called *positive afterimages* of the individual stills, fill in the gaps between the images to produce the perception of a continuously changing image. Peter Roget (of *Roget's Thesaurus* fame) presented the idea of impressions of light being retained on the retina in 1824 [35]. But persistence of vision is not the same as perception of motion. Rotating a white light source fast enough will create the impression of a stationary white ring. Although this effect can be attributed to persistence of vision, the result is static. The sequential illumination of a group of lights typical of a movie theater marquee produces the illusion of a lighted object circling the signage. Motion is perceived, yet persistence of vision does not appear to be involved because no individual images are present. Recently, the causality of the (physiological) persistence of vision mechanism has been called into question and the perception of motion has been attributed to a (psychological) mechanism known as the *phi phenomenon* (as is the case in the movie marquee example given above). A related phenomenon, for example the apparent motion of a disk traveling between two flickering disks, is referred to as *beta movement* [1] [2] [13] [39].

Whatever the underlying mechanism is, the result is that in both film and video, a sequence of images can be displayed at rates fast enough to fool the eye into interpreting it as continuous imagery. When the perception of continuous imagery fails to be created, the display is said to *flicker*. In this case, the animation appears as a rapid sequence of still images to the eye–brain complex. Depending on conditions such as room lighting and viewing distance, the rate at which individual images must be played back in order to maintain the perception of continuous imagery varies. This rate is referred to as the *critical flicker frequency* [8].

While perception of motion addresses the lower limits for establishing the perception of continuous imagery, there are also upper limits to what the eye can perceive. The receptors in the eye continually sample light in the environment. The limitations on motion perception are determined, in part, by the reaction time of those sensors and by other mechanical limitations such as blinking and tracking. If an object moves too quickly with respect to the viewer, then the receptors in the eye will not be able to respond fast enough for the brain to distinguish sharply defined, individual detail; *motion blur* results [11]. In a sequence of still images, motion blur is produced by a combination of the object's speed and the time interval over which the scene is sampled. In a still camera, a fast-moving object will not blur if the shutter speed is fast enough relative to the object's speed. In computer graphics, motion blur will never result if the scene is sampled at a precise instant in time; to compute motion blur, the scene needs to be sampled over an interval of time or manipulated to appear as though it were [21] [32]. (See [Appendix A.3](#) for a discussion of motion blur calculations.) If motion blur is not calculated, then images of a fast-moving object can appear disjointed, similar to viewing live action under the effects of a strobe light. This effect is often referred to as *strobing*. In hand-drawn animation, fast-moving objects are typically stretched in the direction of travel so that the object's images in adjacent frames overlap [49], reducing the strobing effect.

As reflected in the previous discussion, there are actually two rates of concern. One is the *playback* or *refresh* rate—the number of images per second displayed in the viewing process. The other is the *sampling* or *update* rate—the number of different images that occur per second. The playback rate is the rate related to flicker. The sampling rate determines how jerky the motion appears. For example, a television signal conforming to the National Television Standards Committee (NTSC) format displays images at a rate of roughly 30 frames per second (fps),² but because it is *interlaced*,³ *fields* are played at 60 frames per second to prevent flicker under normal viewing conditions [34]. In some programs (e.g., some Saturday morning cartoons) there may be only six different images per second, with each image repeatedly displayed five times. Often, lip-sync animation is drawn *on twos* (every other frame) because drawing it *on ones* (animating it in every frame) makes it appear too hectic. Film is typically shown in movie theatres at playback rates of 24 fps (in the United States) but, to reduce the flicker, each frame is actually displayed twice (*double-shuttered*) to obtain an effective refresh rate of 48 fps. On the other hand, because an NTSC television signal is interlaced, smoother motion can be produced by sampling the scene every 60th of a second even though the complete frames are only played back at 30 fps [8]. Computer displays are typically progressive scan (*noninterlaced*) devices with refresh rates above 70 fps [34]. See [Appendix B.10](#) for some details concerning various film and video formats.

The display and perception of animation using a sequence of still images imposes certain requirements on how those images are computed and played effectively. Understanding the operation, limits, and trade-offs of the human visual system are essential when making intelligent decisions about designing any type of visual and auditory content, including computer animation.

²More accurately, the format for broadcast television system, established by the NTSC, specifies a frame rate of 29.97 fps [29].

³An *interlaced* display is one in which a frame is divided into two *fields*. Each field consists of odd or even numbered scanlines. The odd and even fields are displayed in alternate scans of the display device [8].

1.2 The heritage of animation

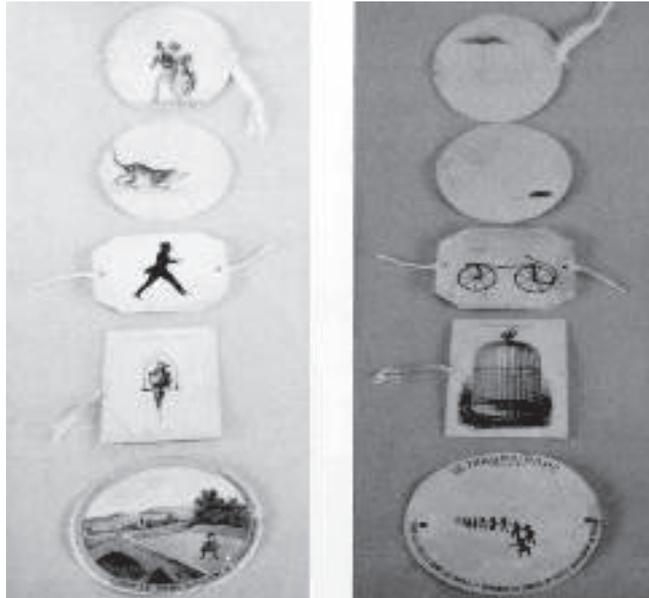

In the most general sense, *animate*⁴ means “give life to” and includes live-action puppetry such as that found on *Sesame Street* and the use of electromechanical devices to move puppets, such as *animatronics*. History is replete with attempts to bring objects to life. This history is a combination of myth, deception, entertainment, science, and medicine. Many of the references to animation are in the form of stories about conjuring a life force into some humanoid form: from Pygmalion to Prometheus to Wagner’s homunculus in Goethe’s *Faust* to Shelley’s Dr. Frankenstein. Some of the history is about trying to create mechanical devices that mimic certain human activity: from Jacques Vaucanson’s mechanical flute player, drummer, and defecating duck in the 1730s to Wolfgang von Kempelen’s chess player in 1769 to Pierre Jaquet-Droz’s writing automaton of 1774 to the electromechanical humanoid robots (*animatronics*) popular today. The early mechanisms from the 1700s and 1800s were set in the milieu of scientific debate over the mechanistic nature of the human body (e.g., *L’Homme Machine*, translated as *Man a Machine*, was written by Julien Offray de La Mettrie in 1747 and was quite controversial). This activity in humanoid mechanical devices was propelled by a confluence of talents contributed by magicians, clock makers, philosophers, scientists, artists, anatomists, glove makers, and surgeons (see Gaby Wood’s book for an entertaining survey on the quest for mechanical life [50]). Here, however, the focus is on devices that use a sequence of individual still images to create the effect of a single moving image, because these devices have a closer relationship to hand-drawn animation.

1.2.1 Early devices

Persistence of vision and the ability to interpret a series of stills as a moving image were actively investigated in the 1800s [5], well before the film camera was invented. The recognition and subsequent investigation of this effect led to a variety of devices intended as parlor toys [23] [38]. Perhaps the simplest of these early devices is the *thaumatrope*, a flat disk with images drawn on both sides with two strings connected opposite each other on the rim of the disk (see Figure 1.1). The disk could be quickly flipped back and forth by twirling the strings. When flipped rapidly enough, the two images appear to be superimposed. The classic example uses the image of a bird on one side and the image of a birdcage on the other; the rotating disk visually places the bird inside the birdcage. An equally primitive technique is the *flip book*, a tablet of paper with an individual drawing on each page. When the pages are flipped rapidly, the viewer has the impression of motion.

One of the most well known early animation devices is the *zoetrope*, or wheel of life. The zoetrope has a short fat cylinder that rotates on its axis of symmetry. Around the inside of the cylinder is a sequence of drawings, each one slightly different from the ones next to it. The cylinder has long vertical slits cut into its side between each adjacent pair of images so that when it is spun on its axis each slit allows the eye to see the image on the opposite wall of the cylinder (see Figure 1.2). The sequence of slits passing in front of the eye as the cylinder is spun on its axis presents a sequence of images to the eye, creating the illusion of motion.

⁴A more restricted definition of *animation*, also found in the literature, requires the use of a sequence of stills to create the visual impression of motion. The restricted definition does not admit techniques such as animatronics or shadow puppets under the rubric animation.

Related gizmos that use a rotating mechanism to present a sequence of stills to the viewer are the *phenakistoscope* and the *praxinoscope*. The phenakistoscope also uses a series of rotating slots to present a sequence of images to the viewer by positioning two disks rotating in unison on an axis; one disk has slits, and the other contains images facing the slits. One sights along the axis of rotation so the slits pass in front of the eye, which can thus view a sequence of images from the other disk.
